

main sheet body and the sub-sheet body are bonded only at each peripheral edge and are not bonded (non-stuck) in some area from the inner peripheral edge to the inside.

[0020] Here, since both sheet bodies are bonded at the peripheral edges, there may be deformation generated in accordance with the bonded state. Specifically, if a wearer having the labia of depth more than the height of the long convex area, the long convex area and surroundings of the main sheet body facing the body side form a long convex area with height sufficient to the depth of the labia of the wearer so as to be inserted between the labia. Only the peripheral edge of the sub-sheet body facing the clothing side which is bonded with the main sheet body is pulled to the body side so that the sub-sheet body as a whole becomes a convex shape facing the opposite side from the body side. Therefore, the sub-sheet body is not to be inserted between the labia.

[0022] If a wearer having the labia of depth less than the height of the long convex area, a part of the long convex area formed in the main sheet body is inserted between the labia but surrounding area of the long convex area is not inserted between the labia. Hence, the peripheral edge of the sub-sheet body is not pulled towards the body side. Therefore, the sub-sheet body remains almost in the original shape when the interlabial pad is worn.

provide the bonding area other than a position of bonding area where the mini sheet piece and the sub-sheet body are bonded. Thereby, a portion around the peripheral edge of the interlabial pad where both bonding areas are provided with more stiffness can be prevented so that the interlabial pad keep the flexibility to make a preferable wear feeling.

[0028] According to still another implementation of an interlabial pad, the main sheet body and the sub-sheet body are bonded at each longitudinal side edge; and wherein at least either sleeve portion in the lateral direction is non-bonded; and wherein the non-bonded sleeve portion comprises a sleeve opening that forms a finger insertion opening in which a finger is inserted.

[0029] In the interlabial pad according to the present invention, at least one of the sleeve portions of the main sheet body or the sub-sheet body is not bonded in the lateral direction so that it makes a sleeve opening to form a finger insertion opening (see FIG. 11) between the main sheet body and the sub-sheet body where a finger can be inserted.

[0030] Since only at left and right side edges of the main sheet body and the sub-sheet body are bonded in the longitudinal direction, a long hollow space is formed between the main sheet body and the sub-sheet body under the long convex area formed on the main sheet body. The long hollow space makes a finger insertion space where a finger can be inserted.

[0031] When both sleeve portions of the main sheet body and the sub-sheet body are non-bonded in the lateral direction, space for finger insertion makes a through hole (like a tunnel) and, when one of the sleeve portions is bonded, space for finger insertion makes a like cave with a closed end.

[0032] In an implementation of the present invention, "side portion" of the main sheet body or the sub-sheet body in the longitudinal direction includes not only the area corresponding to the peripheral edge of the interlabial pad but also some area surrounding the peripheral edge where the main sheet body and the sub-sheet body can be bonded.

[0033] In the interlabial pad according to the present invention as described, since the main sheet body and the sub-sheet body are bonded to form the finger insertion opening connected to space for finger insertion, the interlabial pad can be temporarily fixed to a fingertip by inserting a finger into the finger insertion opening.

[0034] Then, when a finger is inserted, a fingerprint side of a fingertip from the first joint, where many receptors having a keen sense are scattered can be brought into contact with an opposite face on the back side sheet from the body side face of the main sheet body. The long convex area having an absorbing spot can be precisely led to the ostium vagina of a concave shape by moving the interlabial pad in contact with concave or convex surface structures of the labia. As described, in accordance with the present invention, the interlabial pad can be easily and precisely worn between the labia.

[0035] After wearing, since each surface, between which the top of the long convex area is located, collapses inwards so as to fill the space inside the long convex area, the foreign feeling at the time of wearing the interlabial pad can be drastically diminished.

[0036] According to an implementation of an interlabial pad, the main sheet body comprises a plurality of main sheet bodies, each of which are bonded together at each longitudinal side edge and at least either sleeve portion in the lateral direction is non-bonded so as to form a finger insertion opening, in which a finger can be inserted.

[0037] In the interlabial pad according to the present invention, there are a plurality of main sheet bodies so that a finger insertion opening is formed between each of the main sheet bodies. Therefore, a wider selection of finger insertion openings can be provided when a wearer inserts a finger such that the wearer can wear the interlabial pad comfortably according to her labia depth. If absorbent bodies are contained respectively in a long convex area and extended areas of a first main sheet body facing the body side, and if absorbent bodies are contained only in long convex areas of a second and third main sheet bodies positioned on the opposite side from the body side, the interlabial pad

which does not give a foreign feeling to the wearer can be provided while the menstrual blood absorbance efficiency near the ostium of vagina is improved.

[0038] According to an implementation of an interlabial pad, a mini sheet piece is fixed on the back side sheet of the sub-sheet in the clothes side, and the mini sheet piece forms a finger insertion opening between the back side sheet and the mini sheet piece.

[0039] In the interlabial pad according to the present invention as described, the first finger insertion opening and a first finger insertion space connected thereto are formed between the main sheet body and the sub-sheet body, and the second finger insertion opening and a second finger insertion space connected thereto are formed between the sub-sheet body and the mini sheet piece. A wearer having her labia of shallow depth can insert her finger into the first finger insertion opening towards the first finger insertion space and, while she makes her finger cushion touch the opposite side face from the body side face of the back surface side sheet of the main sheet body, lead the long convex area towards the inside between the labia. As a result, only a part of the long convex area, which can be inserted between the labia, can be fitted between the labia.

[0040] On the other hand, a wearer having her labia of deep depth can insert her finger into the second finger insertion opening toward the second finger insertion space and, while she makes her finger cushion touch the opposite side face from the body side face of the back surface side sheet of the sub-sheet body, properly lead the long convex area towards the inside between her labia. Thereby, the whole long convex area can be fitted between the labia.

[0041] As described, in an implementation of the present invention, the interlabial pad has two kinds of finger insertion openings so that the wearer can provide the interlabial pad suitable for her own labia depth by selecting either finger insertion opening according to the size of her labia when she wears the interlabial pad. Furthermore, a manufacture does not have to make various types of interlabial pads corresponding to individual differences in the labia depth.

[0042] According to an implementation of an interlabial pad, the long convex area is composed of a bent portion formed by bending the main sheet body.

[0043] In the interlabial pad according to an implementation of the present invention as described, the long convex area may be formed by merely bending the main sheet body itself so that it can be easily deformed by an external pressure.

[0044] On the contrary, if a ready-made projection is simply provided on the body side face of the interlabial pad, the projection may not necessarily fit to all wearers with individual differences in the shape of their labia. For example, if the labia depth of the wearer is more than the height of the projection, the projection can fill only a portion of the inside of the labia and thereby leave space between the top of the projection and the ostium vaginae. On the other hand, if the labia depth of the wearer is less than the height of the projection, the whole projection can be inserted between the labia. However, the portion other than the projection is also inserted between the labia so that the projection with unnecessary thickness is to be inserted between the labia. As a result, wear feeling is notably deteriorated.

[0045] In this respect, in the interlabial pad according to an implementation of the present invention, the long convex area provided on the main sheet body is formed by merely bending the main sheet body itself so that it can easily deformed according to the labia depth of the wearer. Consequently, the interlabial pad can be used regardless of the differences in the labia depth of the wearers.

[0046] For example, when a wearer having her labia depth less than the height of the long convex area wears the pad, only the long convex area of the main sheet body is fitted between labia. The long convex area is formed by merely bending the main sheet body so that the portion which is not fitted between the labia can be flexibly deformed so as to correspond to the shape near the labia.

[0047] In this respect, it is remarkably distinctive from the case where the ready-made projection is formed by laminating the absorbent bodies. Also, for a wearer with deep labia depth, the interlabial pad according to the present invention can be flexibly applied. For example, if the neighboring substantially flat area as well as the main sheet body is fitted between the labia, the wearer does not feel foreign feeling since the flat area is deformed so as to be in one body with the long convex area.

[0048] The above-described interlabial pad according to an implementation of the present invention can be made more applicable to different labia shapes of different individuals if more flexible materials are used to enable the pad to be easily deformed.

[0049] According to another implementation of an interlabial pad, the long convex area is formed with a shorter top length than a bottom length in the longitudinal direction; and wherein the sleeve opening is formed with both side edges sloped from a bottom to a top.

[0050] In the interlabial pad according to an implementation of the present invention, the longitudinal length at the top of the long convex area is shorter than that at the bottom. In other words, the entrance opening of a long hollow space formed under the long convex area, that is, the finger insertion opening formed between the main sheet body and the sub-sheet body is formed with its both edges sloped from the bottom towards the top that has a shorter length than the bottom. Accordingly, the finger insertion opening is to be provided wider compared to the case where the finger insertion opening is simply formed perpendicular to the main sheet body. Therefore, compared to a finger insertion opening with simply vertical edges to the main sheet body, the finger insertion opening according to the present invention is larger. If both side edges of another finger insertion opening are formed sloping from the top having longer length towards the bottom as opposed to the present invention, finger insertion into the opening may be blocked by the main sheet body. As described, according to the present invention, a smooth and easy finger insertion can be achieved.

[0051] Furthermore, by shortening the top of the long convex area, the contact area of the

easily generated between the substantially flat area of the surface side sheet of the main sheet body and the surface of the pudenda, which may cause leakage of menstrual blood through the gap. Also, if the height is shorter than 5 mm, the long convex area on the main sheet body can not be sufficiently fitted between the labia. Since the contact area with the labia is decreased, it may be more likely for the product to fall off the labia. In addition, the average value of the labia depth of pudenda among Japanese female is about 17 mm so that the more preferable range is from 10 to 20 mm.

[0056] The length of the bottom edge of the substantial triangle of the long convex area in the width direction is preferable to be about 1 to 20 mm and more preferable to be about 2 to 10 mm. If the length is longer than 20 mm, the top corner of the substantial triangle becomes too obtuse so that it may be hard to fit the long convex area between the labia of the female pudenda at the time of wearing the pad. Therefore, it is more likely that wearing becomes troublesome or that a fitted pad may shift from the right position. Also, if the length is shorter than 1 mm, the top corner of the substantial triangle becomes too acute so as to give a foreign feeling to the wearer when she uses the product.

[0057] In this respect, in an implementation of the present invention, the long convex area is formed within the preferable range so that the interlabial pad is formed to give the wearer an excellent wear feeling with high degree of contact to the labia.

[0058] In this Specification, "lateral cross section" means a cross section vertical to the surface forming the interlabial pad and a cross section along the direction substantially vertical to the finger insertion direction.

[0059] According to an implementation of an interlabial pad, a lateral cross sectional area of the long convex area in the lateral direction is at least 1 cm².

[0060] In the interlabial pad according to an implementation of the present invention, the longitudinal cross-sectional area of the above-described long convex area is large enough for a female in general to insert her finger so that she can easily insert her finger into and

remove it out of the inside of the long convex area. Thereby, wearing time can be shortened and it is less likely that the fitted interlabial pad may be shifted from the right position.

[0061] According to still another implementation of an interlabial pad, a lateral cross sectional area of the long convex area becomes substantially-continuously decreased as the area is taken from one end to the other end along the longitudinal direction.

[0062] In the interlabial pad according to an implementation of the present invention, since the finger insertion space becomes smaller towards the other end as the finger has a lateral cross section area smaller towards the fingertip, the inserted finger fits well to the inner wall of the long convex area. Thereby, since it can prevent the finger from playing in the long hollow space, the finger may have a contact area with the back side sheet of the main sheet body so that a large amount of contact area can be obtained. Therefore, while the interlabial pad is being worn, the concave shape ostium vagina can be located precisely by sensing the concave and convex of the labia via over the main sheet as the interlabial pad is in contact with the labia.

[0063] In an implementation of the present invention, "to become smaller substantially-continuously means to become gradually smaller on the average and, as long as it becomes gradually smaller as a whole, a part of the area may become larger or stay equal.

[0064] According to another implementation of an interlabial pad, the interlabial pad is a sanitary-napkin-coexisting-interlabial pad that is used together with a sanitary napkin.

[0065] In the interlabial pad according to an implementation of the present invention as described, even if it is used together with a sanitary napkin, a negative effect on the wear feeling may not arise and it may be less likely to suffer from rash or stuffy feeling.

[0066] In other words, some sanitary napkin users use several pieces of napkins layered together when they have a large quantity of menstrual blood. However, they may feel

uncomfortable because of stiffness of the napkins, which further affect the external appearance. Also, the layered sanitary napkins are put on one after another even near the ostium vaginae where the layered napkins are not needed, which causes rash and stuffy feeling.

[0067] In this respect, with an implementation of the present invention, the sanitary product is layered only on the labia and its surroundings so that there is not a negative effect on the wear feeling and the external appearance. Also, rash and stuffy feeling in the buttock and its surroundings can be decreased.

[0068] Furthermore, in the case of replacement, it is possible to change only the interlabial pad without changing the sanitary napkin according to the present invention. Therefore, the wearer does not have to carry around the sanitary napkins which are large enough to be noticed. The sanitary napkins herein may include an absorption sheet for vaginal discharge as well as a napkin sold for absorbing menstrual blood.

[0069] (12) According to still another implementation of an interlabial pad, the interlabial pad includes an incontinent-interlabial pad for incontinence.

[0070] According to an implementation of the interlabial pad, the pad can be used for incontinence absorb pad. Since both ostium vaginae where the menstrual blood is discharged and urethral meatus where urine is discharged are located between labia, the interlabial pad of the present invention may be used between labia to absorb urine.

[0071] As described hereinbefore, the pad of an implementation of the present invention can absorb urine around labia, especially around the urethral meatus and is useful for the absorbing pad for incontinence, especially for a light incontinence.

[0072] (13) According to another implementation of an interlabial pad, the interlabial pad comprises a vaginal-discharge interlabial pad for absorbing vaginal discharge.

[0073] In accordance with an implementation of the present invention, the interlabial pad can be used for the pad of absorbing the vaginal discharge. The interlabial pad is used by being inserted between labia and can absorb the excretion (vaginal discharge) other than the menstrual blood from ostium vaginae (for absorbing the vaginal discharge).

[0074] As described above, since the pad can absorb the vaginal discharge in order to decrease the wearer's discomfort, it is useful for the user who is not menstruating.

[0075] (14) A wrapping body includes a wrapping container containing the interlabial pad where the interlabial pad is contained in the wrapping container for individual wrapping.

[0076] According to an implementation of the present invention, each interlabial pad may be wrapped individually so that an individually-wrapped interlabial can be carried independently for use. Hence, as opposed that a plurality of the interlabial pad are wrapped in the same wrapping container, it is cleaner and more convenient to handle each pad.

[0077] A wrapping body includes a wrapping container the interlabial pad where the interlabial pad is contained for individual wrapping in an orthogonal direction to the wrapping container.

[0078] According to an implementation of the present invention, the interlabial pad is wrapped without being aligned to the wrapping container. Therefore, the wrapping body is formed so that the first finger insertion opening formed between the main sheet body and the sub-sheet body and the second finger insertion opening formed by the mini sheet piece are to be opened towards the wearer when the wearer opens the wrapping container. Therefore, the wearer's opening direction and finger insertion direction can be made in the same direction so that the wearer can insert the finger easily.

[0079] Furthermore, by changing the folding state of the interlabial pad to be wrapped or

by indicating the opening direction through drawing a design or character, the wearer can easily select a finger insertion opening according to her own labia depth even if the interlabial pad is individually wrapped according to the present invention.

[0080] A wrapping body includes a wrapping container containing the interlabial pad where the interlabial pad is contained for individual wrapping in the wrapping container; and a tear-opening portion of the container is indicated by a picture or a character.

[0081] According to an implementation of the present invention, the positions of the first finger insertion opening formed between the main sheet body and the sub-sheet body and the second finger insertion opening formed by the mini sheet piece can be recognized at a glance without opening the wrapping container. Therefore, the wearer can perform finger insertion to the proper finger insertion opening more easily according to her own labia depth.

[0082] In this case, through providing the above-described design and character with the house mark or the company name, in addition to the above-described effect (indication of the finger insertion opening), an advertisement effect and a quality assurance effect can be expected.

BRIEF DESCRIPTION OF THE DRAWINGS

[0083] FIG. 1 is a schematic perspective view showing the top face (body side surface) of an interlabial pad according to the embodiment;

[0084] FIG. 2 is a schematic perspective view showing the bottom face (opposite side surface to body) of the interlabial pad according to the embodiment;

[0085] FIGS. 3(A) and (B) illustrate the interlabial pad according to the embodiment to which a plurality of mini sheet pieces are attached;

[0086] FIG. 4 is a cross section of the interlabial pad according to the embodiment taken along the line I - I shown in FIG. 1;

[0087] FIG. 5 is an explanatory illustration for describing a long convex area of the interlabial pad according to the embodiment;

[0088] FIG. 6 is an explanatory illustration for describing that the lateral cross sectional areas of the hollows on both edges of the long convex area are different;

[0089] FIG. 7 is an explanatory illustration for describing the whole girth inside a second finger insertion opening of the mini-sheet attached to the interlabial pad according to the embodiment;

[0090] FIG. 8 is an illustration showing the state where the mini sheet piece attached on the interlabial pad according to the embodiment has a length of 10% or more in the longitudinal direction;

[0091] FIGS. 9 (A)-(C) illustrate the unbonded position in the back surface side of the mini sheet piece attached on the interlabial pad according to the embodiment;

[0092] FIGS. 10(A)-(D) illustrate cross-sectional drawings of the attachment position of the mini-sheet on the interlabial pad according to the embodiment;

[0093] FIG. 11 is an explanatory illustration for describing the state when inserting the forefinger from the first finger insertion opening to the hollow space at the time of using the interlabial pad according to the embodiment;

[0094] FIG. 12 is an explanatory illustration for describing the state when inserting the forefinger to the second finger insertion opening at the time of using the interlabial pad according to the embodiment;

[0095] FIGS. 13(A)-(B) illustrate that the first finger insertion opening and the second finger insertion opening face towards the same direction;

[0096] FIG. 14 is an illustration showing the state when wearing the interlabial pad between the labia according to the embodiment;

[0097] FIG. 15 is a front cross section showing the state of the mini sheet piece after wearing the interlabial pad according to the embodiment;

[0098] FIG. 16 is an explanatory illustration showing the state when removing the interlabial pad by pulling the mini sheet piece according to the embodiment;

[0099] FIGS. 17(A)-(B) illustrate a cross section showing the wearing state of the interlabial pad having a ready-made projection;

[0100] FIG. 18 is a cross section showing the state when the interlabial pad according to the embodiment is used by a wearer with a short labia depth;

[0101] FIG. 19 is a cross section showing the state when the interlabial pad according to the embodiment is used by a wearer with a long labia depth;

[0102] FIG. 20 is an illustration showing the state of experiment on measurement of separation force of an adhesive;

[0103] FIG. 21 is an illustration showing the state of experiment on measurement of shearing strength of the adhesive;

[0104] FIGS. 22(A)-(B) illustrate the state where the interlabial pad according to the embodiment is folded and wrapped individually;

[0105] FIGS. 23(A)-(B) illustrate the state where the interlabial pad according to the

described. FIG. 5 is an explanatory illustration for describing the long convex area 3 of the interlabial pad 1 according to the embodiment. FIG. 6 is an explanatory illustration for describing that the lateral cross sectional areas of the hollow part at both ends of the long convex area 3 of the interlabial pad 1 according to the embodiment are different.

[0121] As shown in FIG. 5, the long convex area 3 forming a first finger insertion opening 19A is formed in such a manner that the length of the top 3a is shorter than that of the bottom 3b in the longitudinal direction. Hence, in the finger insertion opening 19A of the long convex area 3, the edges on both sides are formed to be sloping from the bottom towards the top. Therefore, a wearer can insert the finger inside the finger insertion opening 19A without an interruption by the edges on both sides and pass through under the top 3a into the hollow part 5. Having the short top 3a means a decrease in the contact area of the finger cushion of inserted finger. In other words, the friction drag generated between the finger and the inner wall of the long convex area 3 is to be decreased when pulling out the finger from the hollow part 5 after wearing the interlabial pad 1 between the labia. As a result, it can drastically decrease the position shift of the interlabial pad 1 after wearing.

[0122] Also, the finger insertion opening 19A is substantially triangular and the lateral cross sectional area of the hollow part 5 continued therefrom in the lateral direction is 1 cm² or more. With this structure, the finger insertion opening 19A can be maintained to be wide-open to some extent.

[0123] The lateral cross sectional area of the long convex area 3 in the lateral direction, as shown in FIG. 6, is formed in such a manner that one of the end 5b from the other end 5a becomes sub-continuously smaller in the longitudinal direction. With this structure, the shape of the finger in which the lateral cross sectional area becomes smaller towards the fingertip fit to the shape of the hollow part 5. Therefore, the fingertip can be easily kept in contact with the opposite side surface to the body 12a (see FIG. 4) of the back side sheet 12 of the main sheet body 2.

[0124] [Mini Sheet Piece]

[0125] Next, the attachment state of the mini sheet piece 14 will be described. In the embodiment, as shown in FIG. 2, the mini sheet piece 14 is bonded with the back side sheet 62 by the bonding area 17 in the outer edge of the back side sheet 62 and the area from the outer edge to the inside is not bonded. Hence, the mini sheet piece 14 is attached over the area from one side of the back side sheet 62 to the other side thereby forming a hollow part 7 to be a second finger insertion space over the area from one side to the other side.

[0126] In the embodiment, one of the sleeve portions 14b of the mini sheet piece is bonded with the back side sheet 62 in the lateral direction. However, it can be also prepared unbonded. In this case, the above-described hollow part 7 becomes a elongated space with both open ends (like a tunnel).

[0127] In the interlabial pad 1 according to the embodiment, the mini sheet piece 14 is attached so that the finger insertion opening 19B has an aperture large enough for the fingerbreadth in the direction of the finger nail width. Thereby, the flat-shaped fingertip may be inserted and its flat face may contact the sheet surface without being tilted against the sheet surface. In this respect, compared to an incontinence support pad of the related art (JP Patent Hei 6-506368), the easiness of finger insertion is remarkably improved. In other words, in the incontinence support pad of the related art, a finger opening 70 (code 76 in the above-described Application) is closed (see FIG. 26, which corresponds to FIG. 20 in the above-described Application) in the normal state. Therefore, first, a wearer inserts a finger in the direction at a right angle to the incontinence support pad (see FIG. 27, which corresponds to FIG. 22 in the above-described Application) and then turns the finger so that the finger cushion can be faced to the incontinence support pad side.

[0128] On the contrary, in the interlabial pad 1 according to the embodiment, unlike the incontinence support pad of the related art in which the aperture of the fingerbreadth is secondarily formed in the direction of the surface of the back side sheet, the finger

insertion opening 19B which is suitable for finger insertion is primarily formed so as to be able to insert the finger naturally. Therefore, the wearer of the interlabial pad 1 can specify the direction of the finger insertion. As a result, the finger cushion naturally detects the wearing point so that precise wearing of the pad between the labia can be more easily achieved.

[0129] FIG. 7 is a sectional cross section of a part of the interlabial pad 1 in the lateral direction taken out from the interlabial pad 1 for specifically describing the whole girth inside the second finger insertion opening 19B". In FIG. 7, the part unnecessary for describing the length of "the whole girth inside the second finger insertion opening 19B" is shown by an alternate long and short dash line. "The whole girth inside the second finger insertion opening 19B" is a distance denoted by "L" in FIG. 7.

[0130] The whole girth inside the above-described second finger insertion opening 19B is preferable to be 30 to 120 mm, and more preferable to be 40 to 80 mm. When the whole girth inside the above-described second finger insertion opening 19B is shorter than 30 mm, the second finger insertion opening itself becomes small causing a difficulty in putting the finger in and out. On the other hand, when it is longer than 120 mm, the interlabial pad 1 can not be fixed to the finger. Therefore, it becomes harder for the finger cushion to be surely in contact with the sheet surface, which causes a problem when wearing. Accordingly, the length "L" in the embodiment is about 40 mm.

[0131] FIG. 8 is an illustration showing the state where the mini sheet piece 14 attached on the interlabial pad 1 according to the embodiment has a length of 10% or more in the longitudinal direction. FIGS. 9(A)-(C) illustrate the position of the nonbonded part in the back side sheet 6 of the mini sheet piece 14 attached to the interlabial pad 1 according to the present invention.

[0132] In the embodiment, as shown in FIG. 2, the nonbonded part of the mini sheet piece 14 and the back side sheet 62 is only one of the sleeve portions 14a which forms the second finger insertion opening 19B. However, the other sleeve portion 14b can be also

portion of the interlabial pad 1 becomes hard thereby influencing the wear feeling. This can be avoided by positioning and fixing the mini sheet piece 14 with the bonding area 17 in the area other than the peripheral edge 65.

[0137] However, as shown in FIG. 10(B), when the bonding area 17 is positioned more outside of the peripheral edge 65 than the peripheral edge 65, as shown in FIG. 10(C), friction is generated by a movement in accordance with the action of the wearer so that it is considered to be possible that the wearer may be irritated.

[0138] As described, when positioning, as shown in FIG. 10(D), it is preferable that the peripheral edge 15 and the bonding area 17 are positioned with some distance from each other and the bonding area 17 is positioned inner side than the peripheral edge 65.

[0139] When attaching the mini sheet piece 14, pressure sensitive hot melt, thermal sensitive hot melt and the like can be used as an adhesive and can be applied on the whole surface, or in line, spiral, dots and the like.

[0140] The mini sheet piece 14 may be cut beforehand so as to fit with the attaching part as described. Also, if the bonding area is positioned in a different position from other sheets, it may be cut together with other sheets.

[0141] [Shape of the Interlabial Pad]

[0142] The shape of the interlabial pad 1 according to the embodiment may be in any shapes such as elliptic-shape, ovoid-shape, gourd-shape, or drop-shape as long as it is suitable to be worn between the labia. However, with the same shape as in the embodiment, it can be provided to easily fit for both the labia and the finger.

[0143] Each sheet of the interlabial pad 1 according to the embodiment is made of a flexible sheet so that freely and elastically deformed by the external pressure. Hence, the shape of the interlabial pad 1 may be deformed on the appearance such as being bent or

by 40 to 80% of a total specific weight per unit area on the body surface side, and to laminate a mixture of rayon with 1.1 to 4.4 dtex fineness and 7 to 51 mm fiber length by 14 to 42% of a total specific weight per unit area and PET with 1.1 to 4.4 dtex fineness and 7 to 51 mm fiber length by 6 to 18% of a total specific weight per unit area on the clothing surface side. After laminating them so that the total specific weight per unit area of the two layers becomes 20 to 60 g/m², the fibers are entangled by water-flow interlacing treatment and then dried to prepare spun lace nonwoven fabric with the thickness of 0.13 to 0.50 mm. The spun lace nonwoven prepared as described is preferable. At this time, by mixing PET on the clothing side, bulkiness can be easily maintained even if the permeable sheet becomes wet. Therefore, adhesion between the inner wall of the labia can be maintained.

[0148] Examples of a perforated plastic sheet which can be used are an air sheet of thermoplastic resin such as polyethylene (PE), polypropylene (PP), and polyethylene terephthalate (PET), and a perforated foamed-material. Also, it is preferable to use it by making it milky by mixing a filler made of titanium oxide, calcium carbonate and the like within the range of 0.5 to 10 weight % if necessary. A perforated film obtained by forming perforation, thermal embossing, machine processing or the like on a thermoplastic film may be used. Furthermore, a composite sheet of the perforated film and nonwoven fabric may be used.

[0149] The material used for the absorbent body 13 and the absorbent body 63 may be any material as long as it is capable of absorbing and holding a liquid (blood). However, it is preferable to use a single material or a mixture of the materials selected from the group comprising pulp, chemical pulp, rayon, acetate, cotton, particulate polymeric absorbent body, fiber polymeric absorbent body, and a composite fiber. The method by which the materials are formed to be the absorbent body is not limited, however, the method such as air-laid, melt-blown, spun lacing, or paper-making method is employed for an absorbent body to be formed into a sheet to be used. Also, cellulose foam, a continuous foam and the like of synthetic resin can be also used as the absorbent body. Furthermore, an absorbent body obtained by grinding and molding the above-described

sheet and the foam can be used.

[0150] It is preferable for the absorbent body, although any material can be used as long as it is capable of absorbing and holding liquid (fluid), to be bulky, hard-to-be deformed, less chemically stimulant, and highly flexible to fit between the labia. Specifically, a nonwoven sheet in which, 50 to 150 g/m² of pulp selected from the range of the fiber length of 1 to 10 mm is laminated on the garment face side and, on the body face side, 150 to 250 g/m² of a mixture obtained by mixing 60 to 90% of rayon with 1.1 to 4.4 dtex fineness and 20 to 51 mm fiber length with 40 to 10% of natural cotton by this mixing ratio is laminated, which then to be formed into a sheet by dotted embossing to have 2 to 10 mm bulkiness, and more preferable to have 3 to 5 mm bulkiness. Thereby, liquid can be easily transmitted from the body face side to the garment face side resulting in the improvement of the absorbing and holding capacity. Furthermore, by providing a mesh spun lace nonwoven fabric of rayon with 1.1 to 4.4 dtex fineness and 25 to 51 mm fiber length by a specific weight per unit area of 15 to 40 g/m², the liquid transmitted from the body face side can be dispersed by the mesh spun lace to be induced to almost all over the region of the pulp layer. Therefore, more liquid can be effectively absorbed.

[0151] The material used for the back side sheet 12 of the main sheet body 2 and the back side sheet 62 of the sub-sheet body 6 are not specifically limited as long as it has a sheet-type structure such as a fabric, nonwoven fabric, or a plastic. However, examples of an impermeable material are an impermeable film mainly made of PE, PP or the like, a breathing resin film, and a material in which a breathing resin film is bonded to the back side of a nonwoven fabric such as a spun bond or spun lace on which water-repellent processing is performed. Considering the degree of softness by which the wear feeling is not influenced, for example, a film obtained by a specific weight per unit area of 15 to 30 g/m² mainly using LDPE (low density polyethylene) is used.

[0152] By preparing the back side sheet 62 of the above-described sub-sheet body 6 using an impermeable material, blood held in the absorbent body 63 can be prevented from leaking out. Also, by preparing it using a wet permeable material, stuffiness can be

decreased when wearing. Thereby, discomfort felt by the wearers can be decreased when wearing. It is more preferable to reduce the contact ratio to decrease the friction drag value by embossing the above-described film to provide convex-shaped projections in order to, when the pad is worn between the labia, decrease the risk of the interlabial pad from being fallen off from the labia due to the high friction caused by the contact between the impermeable sheets, or with a pad used together, an underwear or the like.

[0153] It is preferable to select the material used for the mini sheet piece 14 considering the strength of the material so that it is not damaged when a finger is inserted. It is possible to select with no limitation a single material or the laminated material from the group comprising a nonwoven sheet, an elastic dilation nonwoven fabric, a film, a foam film, an elastic dilation film, a foam sheet, a tissue paper, and the like. A specific example is a film of 15 to 30 μm thickness having an LDPE resin as the main component. Also, the mini sheet piece 14 can be prepared to have the tone of color, design, chroma which are different from those of the back side sheet 62 of the interlabial pad 1 by coloring or printing a design or the like in order for the wearer to be able to easily discriminate the mini sheet piece 14.

[0154] In order to effectively use the interlabial pad 1 according to the present invention, it is also effective to prepare the above-described mini sheet piece 14 to have a characteristic of stretching or elastic dilation in the lateral direction of the back side sheet 12 regardless of the finger size of the wearer.

[0155] In order for the mini sheet piece 14 to have a stretching characteristic, a stretching spun bond nonwoven fabric can be used in which the stress is 0.1 to 0.5 N/25 mm at the time of 5% stretching when being stretched at a constant speed by a stretching speed of 100 m/minute with a grip interval of 100 mm.

[0156] Also, in order for the mini sheet piece 14 to have an elastic dilation characteristic, a fiber sheet or film sheet using thermoplastic elastomer resin may be used. Also, the elastic dilation material such as the thermoplastic elastomer resin or natural rubber may

2 to 10 mm. Furthermore, if the water dispersibility and strength enough for not-causing damage are considered, it is desirable to select the fineness of the fiber (thickness) within the range of 1.1 to 4.4 dtex.

[0164] Also, it is preferable to have a specific weight per unit area of 20 to 60 g/m². The break strength (the break strength when constant-stretching at grip interval of 100 mm and stretching speed at 100 mm/min) of the permeable material in both longitudinal and lateral direction are at least 800 mN/25 mm, and more preferable to be selected from the range of 1000 to 7000 mN/25 mm with the consideration of softness at the time of wearing.

[0165] A specific example of the permeable material is a wet forming spun lace nonwoven fabric prepared by mixing 5 to 10 mm of rayon fiber of 1.1 to 4.4 dtex and wood pulp at 90:10 to 70:30 weight ratio with a specific weight per unit area of 25 to 40 g/m² and the thickness of 0.2 to 0.5 mm. A plurality of pores may be provided on the permeable material. In this case, the pores may be formed to have a diameter within the range of 0.5 to 1.5 mm with the porous area ratio (rate of the porous area per unit area) within the range of 3 to 20%.

[0166] A natural fiber and/or chemical fiber can be used for the absorbent body 13 and the absorbent body 63. Examples of the natural fiber are tissue, ground pulp, air laid pulp which is obtained by chemical bonding water soluble resin, cotton, and the like.

Examples of hydrophilic chemical fiber are rayon which is a regenerated cellulose, feeble rayon, and the like, and examples of synthetic fiber are the one obtained by performing hydrophilic processing on polyester, polypropylene, polyethylene, ethylene vinyl acetate copolymer and the like. Also, examples of synthetic biodegradable fiber are poly lactic acid, polybutylene succinate, and the like, and examples of a water soluble material are carboximethyl cellulose, polyvinyl alcohol, and polyacrylonitrile. Especially, it is preferable to use the natural fiber such as pulp, cotton, or the like, or biodegradable fiber such as rayon, poly lactic acid, or the like. It is also possible to use one of these materials alone or by mixing the materials by a predetermined combination. It is also possible to

combined to be used as a bonding method.

[0173] Specific examples of the wrapping container made of a water soluble material or water dispersible material are a compound material obtained by laminating tissue with a specific weight per unit area of 15 to 40 g/m² and polyvinyl alcohol with a specific weight per unit area of 20 to 50 g/m² and applying silicone of 0.5 to 1 .mu.m on the polyvinyl alcohol side, a spun bond nonwoven fabric, etc. prepared with a specific weight per unit area of 15 to 40 g/m² mainly using poly lactic acid fiber.

[0174] [Size]

[0175] The length of the main sheet body 2 in the lateral direction on the appearance is preferable to be 10 to 60 mm, and more preferable to be 20 to 40 mm. When the length in the lateral direction is longer than 60 mm, the area which is not inserted between the labia is rubbed against the femoral region or the like of the wearer and the friction generated thereby exceeds the holding strength between the both labia so that the interlabial pad may fall off. Also, when the length in the lateral direction is shorter than 10 mm, the area which can be inserted between the labia becomes small thereby reducing the contact area with the inner face of the labia. Thereby, there generates a risk of the interlabial pad being fallen off.

[0176] The above-described "appearance" means the distance between two points with the shortest length (V in FIG. 28). This is to carefully define the length since, in the manufacturing step, there may be a case where the length between the two points in a concave and convex shape is taken as the actual length (W in FIG. 28), that is, the distance between the two points in the state in which the concave and convex shape are unfolded to be flat.

[0177] On the other hand, the length of the main sheet body 2 in the longitudinal direction is preferable to be 50 to 150 mm, and more preferable to be 80 to 120 mm. When the length in the longitudinal direction is longer than 150 mm, friction generated

by the substantial flat area 4 which is not inserted between the labia being rubbed against the underwear or a sanitary napkin exceeds the holding strength of the labia itself so that the interlabial pad 1 may fall off. Also, when the length in the longitudinal direction is shorter than 50 mm, the range of the area of main sheet body 2 which can be inserted between the labia becomes small thereby reducing the contact area between the labia and the main sheet body 2. Thereby, there generates a risk of the interlabial pad 1 being fallen off.

[0178] The length of the sub-sheet body 6 in the lateral direction on the appearance is preferable to be 10 to 60 mm, and more preferable to be 30 to 40 mm. When the length in the lateral direction is longer than 60 mm, the end of the substantial flat area 4 is rubbed against the femoral region of the wearer thereby generating friction. The generated friction exceeds the holding strength of the both labia so that the interlabial pad 1 may fall off. Also, when the length of the sub-sheet body 6 in the lateral direction is shorter than 10 mm, it becomes shorter on the appearance than the maximum value of the length of the unbonded part, which is not inserted between the labia, in the main sheet body 2 in the lateral direction. As a result, the range of the substantial flat area 4 in the lateral direction functioning to absorb blood which cannot be completely absorbed in the long convex area 3 of the main sheet body 2 becomes insufficient for covering the pudenda.

[0179] The above-described "appearance" means the distance between two points with the shortest length. This is to carefully define the length since, in the manufacturing step, there may be a case where the distance" between the two points in a concave and convex shape (that is, the distance between the two points in the state in which the concave and convex shape are unfolded to be flat) is taken as the actual "length".

[0180] On the other hand, the length of the sub-sheet body 6 in the longitudinal direction is preferable to be 60 to 160 mm, and more preferable to be 90 to 130 mm. When the length of the sub-sheet body 6 in the longitudinal direction is longer than 160 mm, friction may be easily generated since the sub-sheet body 6 keeping a plan shape is rubbed against the napkin or the underwear, and the generated friction exceeds the

depth. In other words, if the wearer has shallow labia depth, the finger can be inserted from the first finger insertion opening 19A to the hollow part 5 continued therefrom. On the contrary, if the wearer has deep labia depth, the finger can be inserted from the second finger insertion opening 19B to the hollow part 7 continued therefrom.

[0185] Specifically, the wearer with shallow labia depth, as shown in FIG. 11, inserts the finger from the first finger insertion opening 19A to the hollow part 5 having its fingerprint side face being in contact with the opposite side surface to body 12a of the back side sheet 12 in the main sheet body 2. In this case, the hollow part 5 becomes smaller in a substantially continuous manner. Therefore, the finger is to be inserted from the sleeve portion 5a with a large lateral cross sectional area to the sleeve portion 5b with small area. Also, the wearer with deep labia depth, as shown in FIG. 12, inserts the finger from the second finger insertion opening 19B to the hollow part 7 having its fingerprint side face being in contact with the opposite side surface to body 62a of the back side sheet 62 in the sub-sheet body 6.

[0186] As described, according to the present invention, when wearing the interlabial pad 1 between the labia, the ostium vagina with a concaved shape can be detected by the finger cushion of finger with a keen sense through the main sheet body 2 or both of the main sheet body 2 and the sub-sheet body 6. Thereby, the interlabial pad 1 can be led so that the long convex area 3 is inserted between the labia.

[0187] When wearing the interlabial pad 1 according to the embodiment, first, the forefinger or middle finger is inserted to the finger insertion opening to hold the product thereby. However, there are two finger insertion openings so that the wearer selects either one in accordance with her own labia depth. In the embodiment, the finger insertion opening 19A and the finger insertion opening 19B are positioned to face in the same direction so that there is no need for the wearer to turn over the whole body of the interlabial pad 1 when selecting either the finger insertion opening 19A or the finger insertion opening 19B. When the finger is inserted to the finger insertion opening 19A, as shown in FIG. 13(A), the finger is to be inserted between the main sheet body 2 and the

sub-sheet body 6 and, when the finger is inserted to the finger insertion opening 19B, the finger is to be inserted between the sub-sheet body 6 and the mini sheet piece 14. Thereby, the interlabial pad 1 is fixed to the fingertip. Incidentally, when wrapping the interlabial pad 1 according to the present invention individually, by positioning the finger insertion opening 19A and the finger insertion opening 19B near the opening section, wearers with any types of the labia depth can easily insert their fingers.

[0188] As described, by inserting the finger to the finger insertion opening 19A or 19B, the fingerprint side surface of a finger from the first joint up, where many receptors exist, comes to be in contact with the opposite side surface to the body 12a of the back side sheet 12. Therefore, when leading the interlabial pad 1 to the labia, as shown in FIG. 14, the opposite side surface to the body 11a of the surface side sheet 11 in the main sheet body 2 is provided to be in contact with labia 18 and, while detecting the concave and convex of the labia 18 by the fingertip with a keen sense, the long convex area 3 formed on the body side surface of the interlabial pad 1 can be surely lead deep into between the labia 18 which is hard to be viewed.

[0189] Inside of the mini sheet piece 14 forming the hollow part 7 which is the gap in the second finger insertion opening is not pasted to the back side sheet 62. Therefore, when the finger is pulled out from the finger insertion opening 19A after wearing the interlabial pad 1, as shown in FIG. 15, the mini sheet piece 14 is loosened in the opposite direction to the body side. Hence, when removing the used interlabial pad 1, the loosened mini sheet piece 14 can be pulled out as shown in FIG. 16. Furthermore, by providing the mini sheet piece 14 using an impermeable or wet permeable material, the interlabial pad 1 can be removed without contaminating the finger even if the wearer grabs the mini sheet piece 14.

[0190] By providing microscopic concaves and convexes in the area in the to be in contact with the finger cushion in the back side sheet 12 of the main sheet body 2 and the sub-sheet body 6, the area can be reduced where the finger cushion side of the fingertip comes to be in contact with the opposite side surface to the body 12a of the back side

sheet 12 and the opposite side surface to the body 62a of the back side sheet 62. As a result, it makes possible to suppress friction and stuck generated between the fingertip and the interlabial pad 1. In this case, there is no chance for the interlabial pad 1 to be fitted in the position which is not the intention of the wearer, which may otherwise occur due to the influence of the state of the fingertip of the wearer, such as the wet environment. Also, the finger can be smoothly pulled out after wearing so that the position shift after wearing can be prevented.

[0191] [Wearing State]

[0192] Next, the wearing state of the interlabial pad 1 according to the embodiment will be described. FIGS. 17(A)-(B) show a cross section of the wearing state of an interlabial pad with a ready-made projection 21. FIG. 18 and FIG. 19 are cross sections showing the wearing state of the interlabial pad according to the embodiment.

[0193] When wearing the interlabial pad 1 with the ready-made projection 21, if the height of the projection 21 and the depth of the labia 18 are not consistent with each other, there tends to be a gap generated between the labia 18 and the interlabial pad 1, which causes a bad wear feeling. In other words, as shown in FIG. 17(A), when the depth of the labia 18 is shorter than the height of the projection 21, the bottom portion of the projection 21 which is not inserted between the labia 18 separates the labia 18 and the part other than the projection 21, which is a flat part 22, thereby generating a gap therebetween. On the other hand, as shown in FIG. 17(B), when the depth of the labia 18 is longer than the height of the projection 21, not only the projection 21 but also the whole thickness of the flat area 22 positioned in the periphery of the projection 21 is inserted in between the labia 18 so that the wearer may feel a strong foreign feeling.

[0194] In this respect, in the interlabial pad 1 according to the present invention, when the height of the long convex area 3 is shorter than the depth of the labia 18, a finger is inserted from the first finger insertion opening 19A to fix the interlabial pad 1 to the fingertip and detect the ostium vagina by having the fingerprint surface of the finger

adhesive beforehand on a part of the surface side sheet 11 of the main sheet body 2 and/or the surface side sheet 61 of the sub-sheet body 6, the fixing and the adhesion of the interlabial pad 1 between the labia can be improved. Thereby, generation of a gap between the body and the interlabial pad due to the body action of the wearer can be prevented.

[0199] As the adhesive agent as described, a gel adhesive, etc. made of water-soluble polymer, a crosslinking agent, a flexibilizer and moisture can be used. Examples of the water soluble polymer used herein is gelatin, polyacrylic acid sodium, polyvinyl alcohol, and carboxymethyl cellulose, etc. Examples of the crosslinking agent are water soluble metallic salt such as calcium chloride and magnesium sulfate and examples of the flexibilizer are glycerol, wax, paraffin, etc.

[0200] As other adhesive agent, so-called a pressure sensitive hot melt can be also used. Incidentally, the pressure sensitive hot melt is mainly formed of synthetic rubber resin such as styrene-isoprene-styrene block copolymer (SIS), styrene-butadiene-styrene block copolymer (SBS), styrene-ethylene-butadiene-styrene block copolymer (SEBS), and styrene-ethylene-propylene-styrene block copolymer (SEPS). The pressure sensitive hot melt adhesive can be obtained by fused-mixing adhesion adder such as terpene resin or rosin resin and a flexibilizer such as wax, etc. to the pressure sensitive hot melt. Also, silicone adhesive agent can be used as other adhesive. An example of the silicone adhesive is a mixture obtained by mixing a crosslinking agent such as metallic salt of platinum, molybdenum, or antimony and a flexibilizer such as ester wax, glycerin, or machine oil, etc.

[0201] If the application stability is taken into consideration, the pressure sensitive hot melt is preferable. More specifically, it is an adhesive agent prepared by fused-mixing 15 to 25 weight % of SEBS, 15 to 35 weight % of flexibilizer, and 40 to 70 weight % of adhesive adder. Also, according to circumstances, it is possible to add antioxidant, antifuorescent or the like within the range of 0.1 to 1.0 weight % to the pressure sensitive hot melt.

[0202] It is preferable to cover the part where the adhesive is applied with a sheet which is obtained by coating silicon resin on a tissue paper, which is a generally obtainable separate paper, or a sheet obtained by coating silicon resin on a film. Thereby, damages or separation of the adhesive part can be prevented while being stored.

[0203] Examples of the manner in which the adhesive is applied are in the form of whole surface application or in dots, mesh, or lines. The application position of the adhesive agent is not specifically limited as long as it enables fixing of the pad to the body. However, specifically considering the existence of the hair-grown part in the area in front of the labia, it is preferable to apply the adhesive near both end sides of the inter labia pad 1 in lines with about 1 to 5 mm width.

[0204] An example of valuation method of the adhesive strength will be described in detail. The valuation method is to measure the separation force (FIG. 20) and the shearing force of the adhesive (FIG. 21). A constant speed expansion tensile tester and a stainless plate of 80 mm.times.50 mm is required as the instruments used therein. As a preparation for the evaluation test, a test piece of a polyethylene film 36 in which an adhesive 37 is applied within the range of 25 mm in width and 50 mm in length is left for 30 minutes at a room temperature of 20.degree. C. beforehand. Subsequently, the polyethylene film 36 is put lightly over a stainless plate 35 with the width being overlapped and the adhesive 37 being in contact with the stainless plate 35, and a 2 kg-roller is applied one way. Then, it is left for 30 minutes at a room temperature of 20.degree. C.

[0205] The test sheet obtained as described is used, and the test condition is provided to be 70 mm chuck interval (grip interval) and 100 mm/min testing speed. In the separation force test of the adhesive, it is separated in the pulling direction B in FIG. 20 and, in the shearing force test of the adhesive, it is pulled in the pulling direction C in FIG. 21.

[0206] In the case where the forces are measured by the measurement method described above, considering the burden imposed on the skin of the wearer, it is preferable that the

insertion opening 19B positioned near the opening section where a character meaning "deep" is put. Thereby, the wearer with the shallow labia depth can insert the finger easily from the finger insertion 19A by opening the wrapping container 40 from the opening section where a character meaning "shallow" is put as shown in FIG. 23A. Then, the wearer with the deep labia depth can insert the finger easily from the finger insertion 19B by opening the wrapping container from the opening section where a character meaning "deep" is put as shown in FIG. 23B.

[0212] [Other Applicable Embodiment of the Interlabial Pad]

[0213] The interlabial pad 1 according to the embodiment, as shown in FIG. 24, can be used together with an ordinal sanitary napkin 30. As for the wearing method, the interlabial pad 1 is fitted in between the labia and the sanitary napkin 30 is fitted to the underwear. By using it together with a sanitary napkin as described, the interlabial pad 1 of the present invention can be effectively used even on a occasion expecting a large quantity of blood.

[0214] Industrial Applicability

[0215] According to the present invention as described, a finger can be inserted to a finger insertion opening provided in an interlabial pad having a long convex area on the body side face. Thereby, the interlabial pad can be fixed and held by the fingertip so that the interlabial pad can be fitted in the appropriate position even in between labia where it is hard to be viewed.

[0216] Also, the above-described finger insertion opening is provided in two areas so that the wearer can select either one according to her own labia depth. In addition, the above-described long convex area are flexibly deformed in accordance with the labia depth of the wearer thereby enabling a close wearing of the interlabial pad in between the labia regardless of the labia depth of the wearer. As a result, leak of blood can be drastically decreased.
